Final Project Specification, Spring 2020

Important Dates:

Proposals due: March 20th, 11:59 PM
Proposal discussions: April 10th at the latest (there will be a web sign-up for times)
Project report due: May 5th, 11:59 PM
Presentation slides due: May 6th, 11:59 PM
Presentations: May 7th and May 12th in-class

Process

The final project in this subject will consist of the following components: proposal and proposal discussion, research project, and project report.

Projects should be completed in teams of two. If your project idea must be executed alone, you must email the course staff at 6.874staff@mit.edu at least one week before the project proposal deadline (March 12th) with a one-paragraph description of the project, and a justification for why the project must be completed alone (e.g. proprietary data). Requests will be reviewed on a case by case basis.

Your team must:

- Make clear in the proposal what the division of labor will be.
- Make clear in the written report what the division of labor actually was (it's fine if it deviates from the proposal, but it must be specific and accurate).
- Be sure that all participants understand all of the work.
- Be sure to cite all papers and websites consulted during the course of your project, as well as to acknowledge others who helped you.

Proposal

The proposal (one per team) will be a written document, 1–2 pages long, outlining the work to be done. It should include a plan with at least 4 intermediate milestones and indicate your internal deadlines for each of those steps. If there are multiple participants, the division of responsibility should be made clear. In addition, please include your assessment of what the "risks" to the

project are: that is, what things do you think might turn out to be more difficult than planned, and what thoughts do you have about how to mitigate the risks?

If you are going to do an empirical study, be sure that you think about what method to use as a "baseline." It might be running a simple off-the-shelf algorithm or comparing it to what happens if you predict the most common class. Remember that almost anything will turn out to be harder and more time-consuming than you expect. Try to arrange your project so your intermediate milestones can serve as alternative finishing points, in case you don't get to the end. It will be much better to turn in a polished version of a small-scale project than to find yourself at the end of the term with a three-quarter implemented system of great depth and scope.

Proposal Review

A proposal interview (one per team) of about 10 minutes will be scheduled for all teams. This is your chance to get feedback on your proposal, with some ideas about how to structure your experiments, etc.

Project Report

The project report (one per team) will be a written document of about 8 pages (about 4 pages if you are approved to do the project on your own) in double-column conference format including whatever graphs and tables that are necessary to make your point. The report is the means by which you communicate the process and results of your project, so it should be clear, coherent, and well written. Do not dump out large quantities of data or code or uninterpreted charts. Emulate the expositional style of a technical conference paper. But, you do not need a detailed related work section. But, be sure to cite and very quickly explain any technical work you referenced in formulating and carrying out your project. Previous work should be referenced in your original proposal, so you do not need to duplicate that in your final report.

The main goals of your report are to make clear what your findings are, why you think they came out the way they did, and why that might be important and to be precise enough to allow someone to replicate your experiments (or verify your proofs).

Projects

You have 4 weeks to do this project, and we expect it to take about 6 person-hours per week; so that's 25 person-hours for a single-person project and 50 person-hours for a two-person project You'll have to make a plan and stick to it, to avoid getting behind and doing a bad rush job at the end.

Here are some ideas for types of projects:

Comparing different methods for a problem This is probably the best option if you don't have a concrete idea of something different to do. This would involve performing a careful comparison of various extant methods and models for a problem in computational biology or healthcare. You would need to characterize and understand the data characteristics/situations for which the different techniques work well (or don't). These two papers are a nice example of the kind of project you should be aiming for (https://bmcgenomics.biomedcentral.com/articles/10.1186/s12864-016-2729-8, https://www.ncbi.nlm.nih.gov/pubmed/20017957).

Apply a technique to new problems: Take one or more of the methods that we have talked about in class, or that we are about to cover, and apply them to a problem. Compare their performance and elucidate why they perform differently if they do. Do they do a good job on the problem? This is most interesting if you can apply it to some other research question or problem you know about. A big issue here is being sure that you can get the data you need.

Propose a new method or variation of existing methods: We have talked about many techniques for solving different problems in computational biology, yet many of them have room for improvement and innovation. Take one or more of the problems that we learned in the class and try to make modifications to the methods or come up with novel methods that could potentially solve the problem better (e.g. better performance, better computational efficiency, better interpretability, better generalizability, etc.). Given that this is a more challenging direction, we will appreciate the novelty and depth of the proposed method even if the results are not perfect. Comparison to baseline methods is also important but it does not need to be as extensive as the first type of project.

You don't necessarily have to implement all (or even any) of the algorithms you use. There are several toolkits available with many learning algorithms already implemented in them. However, if you don't do any implementation yourself, we would expect something much deeper in the way of problem formulation or modeling.

Code Citations

Make completely clear in your paper which software you wrote and which software you used (e.g. external codebases, copied implementation) but did not write.

Project Ideas

Please start thinking of ideas now, and avail yourself of office hours to refine your ideas with the help of a TA. Here are some project areas for your consideration.

1. Compare different approaches to predicting the effects of eQTLs using the CAGI 2016 data.
2. Evaluate different methods of predicting the DNase-seq/ATAC-seq measured accessibility of the genome.
3. Evaluate different experimental design methods for the TF k-mer binding data.
4. Produce a method to predict functional genomic variants.
5. Check out the DREAM challenges (http://dreamchallenges.org) for further ideas for projects on computational biology.

Do not hesitate to contact the teaching staff if we can be of help.
